1	1 Maximum Margin Classifiers		
$y = \mathbf{w}^{\top} \mathbf{x} + b$			
	• R	emember the Perceptron!	
	• If	data is linearly separable	
		- Perceptron training guarantees learning the decision boundary	
	• T	here can be other boundaries	

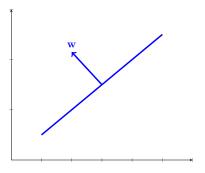

- Depends on initial value for \mathbf{w}
- But what is the best boundary?

1.1 Linear Classification via Hyperplanes

- Separates a *D*-dimensional space into two half-spaces
- Defined by $\mathbf{w} \in \Re^D$
 - Orthogonal to the hyperplane
 - This **w** goes through the origin
 - How do you check if a point lies "above" or "below" \mathbf{w} ?
 - What happens for points **on w**?

For a hyperplane that passes through the origin, a point \mathbf{x} will lie above the hyperplane if $\mathbf{w}^{\top}\mathbf{x} > 0$ and will lie below the plane if $\mathbf{w}^{\top}\mathbf{x} < 0$, otherwise. This can be further understood by understanding that $\mathbf{w}^{\top}\mathbf{x}$ is essentially equal to $|\mathbf{w}||\mathbf{x}|\cos\theta$, where θ is the angle between \mathbf{w} and \mathbf{x} .

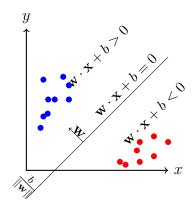

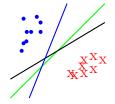

- \bullet Add a bias b
 - -b>0 move along **w**
 - b < 0 move opposite to ${\bf w}$
- How to check if point lies above or below **w**?
 - If $\mathbf{w}^{\top}\mathbf{x} + b > 0$ then \mathbf{x} is above
 - Else, below
- \bullet Decision boundary represented by the hyperplane ${\bf w}$
- For binary classification, w points towards the positive class

Decision Rule

$$y = sign(\mathbf{w}^{\top}\mathbf{x} + b)$$

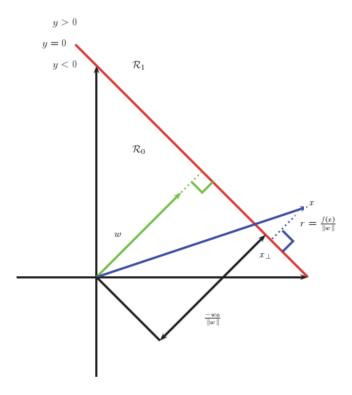

- $\bullet \ \mathbf{w}^{\top} \mathbf{x} + b > 0 \Rightarrow y = +1$
- $\bullet \ \mathbf{w}^{\top} \mathbf{x} + b < 0 \Rightarrow y = -1$
- \bullet $\bf Perceptron$ can find a hyperplane that separates the data
 - ... if the data is linearly separable
- But there can be many choices!
- Find the one with best separability (largest margin)

- \bullet Gives better generalization performance
 - 1. Intuitive reason
 - 2. Theoretical foundations

1.2 Concept of Margin

- Margin is the distance between an example and the decision line
- Denoted by γ
- For a positive point:

$$\gamma = \frac{\mathbf{w}^{\top} \mathbf{x} + b}{\|\mathbf{w}\|}$$

• For a negative point:

$$\gamma = -\frac{\mathbf{w}^{\top} \mathbf{x} + b}{\|\mathbf{w}\|}$$

To understand the margin from a geometric perspective, consider the projection of the vector connecting the origin to a point \mathbf{x} on the decision line. Let the point be denoted as \mathbf{x}' . Obviously the vector \mathbf{r} connecting \mathbf{x}' and \mathbf{x} is given by:

$$\mathbf{r} = \gamma \widehat{\mathbf{w}} = \gamma \frac{\mathbf{w}}{\|\mathbf{w}\|}$$

if \mathbf{x} lies on the positive side of \mathbf{w} . But the same vector can be computed as:

$$r = x - x'$$

Equating above two gives us \mathbf{x}' as:

$$\mathbf{x}' = \mathbf{x} - \gamma \frac{\mathbf{w}}{\|\mathbf{w}\|}$$

Noting that, since \mathbf{x}' lies on the hyperplane and hence:

$$\mathbf{w}^{\top}\mathbf{x}' + b = 0$$

Substituting \mathbf{x}' from above:

$$\mathbf{w}^{\top}\mathbf{x} - \gamma \frac{\mathbf{w}^{\top}\mathbf{w}}{\|\mathbf{w}\|} + b = 0$$

Noting that $\frac{\mathbf{w}^{\top}\mathbf{w}}{\|\mathbf{w}\|} = \|\mathbf{w}\|$, we get γ as:

$$\gamma = \frac{\mathbf{w}^{\top} \mathbf{x} + b}{\|\mathbf{w}\|} \tag{1}$$

Similar analysis can be done for points on the negative side of \mathbf{x} . In general, one can write the expression for the margin as:

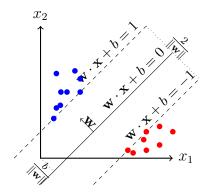

$$\gamma = y \frac{\mathbf{w}^{\top} \mathbf{x} + b}{\|\mathbf{w}\|} \tag{2}$$

where $y \in \{-1, +1\}$.

Functional Interpretation

Margin positive if prediction is correct; negative if prediction is incorrect

From the figure one can note that the size of the margin is $\frac{2}{\|\mathbf{w}\|}$. We can show this as follows. Since the data is separable, we can get two parallel lines represented by $\mathbf{w}^{\top}\mathbf{x} + b = +1$ and $\mathbf{w}^{\top}\mathbf{x} + b = -1$. Using result from (1) and (2), the distance between the two lines is given by $2\gamma = \frac{2}{\|\mathbf{w}\|}$.

2 Support Vector Machines

- ullet A hyperplane based classifier defined by ${\bf w}$ and b
- Like perceptron
- \bullet Find hyperplane with maximum separation margin on the training data
- Assume that data is linearly separable (will relax this later)
 - Zero training error (loss)

SVM Prediction Rule

$$y = sign(\mathbf{w}^{\top}\mathbf{x} + b)$$

SVM Learning

- Input: Training data $\{(\mathbf{x}_1, y_1), (\mathbf{x}_2, y_2), \dots, (\mathbf{x}_N, y_N)\}$
- \bullet Objective: Learn w and b that maximizes the margin

2.1 SVM Learning

- SVM learning task as an optimization problem
- \bullet Find ${\bf w}$ and b that gives zero training error
- Maximizes the margin $(=\frac{2}{\|w\|})$

• Same as minimizing $\|\mathbf{w}\|$

Optimization Formulation

minimize
$$\frac{\|\mathbf{w}\|^2}{2}$$

subject to $y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1, \ n = 1, \dots, N.$

• Optimization with N linear inequality constraint

A Different Interpretation of Margin

- What impact does the margin have on **w**?
- Large margin \Rightarrow Small $\|\mathbf{w}\|$
- \bullet Small $\|\mathbf{w}\| \Rightarrow$ regularized/simple solutions
- Simple solutions \Rightarrow Better generalizability (Occam's Razor)
- Computational Learning Theory provides a formal justification [1]

2.2 Solving SVM Optimization Problem

Optimization Formulation

minimize
$$\frac{\|\mathbf{w}\|^2}{2}$$

subject to $y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1, \ n = 1, \dots, N.$

- ullet There is an quadratic objective function to minimize with N inequality constraints
- "Off-the-shelf" packages quadprog (MATLAB), CVXOPT
- Is that the best way?

3 Constrained Optimization and Lagrange Multipliers

minimize
$$f(x,y) = x^2 + 2y^2 - 2$$
minimize $f(x,y) = x^2 + 2y^2 - 2$

subject to
$$h(x, y) = x + y - 1 = 0$$
.

• Tool for solving constrained optimization problems of differentiable functions

minimize
$$f(x,y) = x^2 + 2y^2 - 2$$

subject to $h(x,y)$: $x + y - 1 = 0$.

• A Lagrangian multiplier (β) lets you combine the two equations into one

$$\underset{x,y,\beta}{\text{minimize}} L(x,y,\beta) = f(x,y) + \beta h(x,y)$$

Solution 1. Writing the objective as Lagrangian.

$$L(x, y, \beta) = 2 - x^2 - 2y^2 + \beta(x + y - 1)$$

Setting the gradient to 0 with respect to x, y and β will give us the optimal values.

$$\frac{\partial L}{\partial x} = -2x + \beta = 0$$

$$\frac{\partial L}{\partial y} = -4y + \beta = 0$$

$$\frac{\partial L}{\partial \beta} = x + y - 1 = 0$$

Multiple Constraints

minimize
$$f(x, y, z) = x^2 + 4y^2 + 2z^2 + 6y + z$$

subject to $h_1(x, y, z)$: $x + z^2 - 1 = 0$
 $h_2(x, y, z)$: $x^2 + y^2 - 1 = 0$.

$$L(x, y, z, \boldsymbol{\beta}) = f(x, y, z) + \sum_{i} \beta_{i} h_{i}(x, y, z)$$

Handling Inequality Constraints

minimize
$$f(x,y) = x^3 + y^2$$

subject to $g(x): x^2 - 1 \le 0$.

• Inequality constraints are **transferred** as constraints on the Lagrangian, α

The Lagrangian in the above example becomes:

$$L(x, y, \alpha) = f(x, y) + \alpha g(x, y)$$
$$= x^3 + y^2 + \alpha (x^2 - 1)$$

Solving for the gradient of the Lagrangian gives us:

$$\frac{\partial}{\partial x}L(x, y, \alpha) = 3x^2 + 2\alpha x = 0$$
$$\frac{\partial}{\partial y}L(x, y, \alpha) = 2y = 0$$
$$\frac{\partial}{\partial \alpha_1}L(x, y, \alpha) = x^2 - 1 = 0$$

Furthermore we require that:

$$\alpha > 0$$

From above equations we get $y=0, x=\pm 1$ and $\alpha=\pm \frac{3}{2}$. But since $\alpha\geq 0$, hence $\alpha=\frac{3}{2}$. This gives x=1, y=0, and f=1.

Handling Both Types of Constraints

minimize
$$f(\mathbf{w})$$

subject to $g_i(\mathbf{w}) \le 0$ $i = 1, ..., k$
and $h_j(\mathbf{w}) = 0$ $j = 1, ..., l$.

Generalized Lagrangian

$$L(\mathbf{w}, \boldsymbol{\alpha}, \boldsymbol{\beta}) = f(\boldsymbol{w}) + \sum_{i=1}^{k} \alpha_i g_i(\mathbf{w}) + \sum_{j=1}^{l} \beta_j h_j(\mathbf{w})$$

subject to, $\alpha_i \geq 0, \forall i$

Primal and Dual Formulations

Primal Optimization

• Let θ_P be defined as:

$$\theta_P(\mathbf{w}) = \max_{\boldsymbol{\alpha}, \boldsymbol{\beta}: \alpha_i > 0} L(\mathbf{w}, \boldsymbol{\alpha}, \boldsymbol{\beta})$$

• One can prove that the optimal value for the original constrained problem is same as:

$$p^* = \min_{\mathbf{w}} \theta_P(\mathbf{w}) = \min_{\mathbf{w}} \max_{\alpha, \beta: \alpha_i \ge 0} L(\mathbf{w}, \alpha, \beta)$$

Consider

$$\theta_{P}(\mathbf{w}) = \max_{\boldsymbol{\alpha}, \boldsymbol{\beta}: \alpha_{i} \geq 0} L(\mathbf{w}, \boldsymbol{\alpha}, \boldsymbol{\beta})$$

$$= \max_{\boldsymbol{\alpha}, \boldsymbol{\beta}: \alpha_{i} \geq 0} f(\mathbf{w}) + \sum_{i=1}^{k} \alpha_{i} g_{i}(\mathbf{w}) + \sum_{i=1}^{l} \beta_{i} h_{i}(\mathbf{w})$$

It is easy to show that if any constraints are not satisfied, i.e., if either $g_i(\mathbf{w}) > 0$ or $h_i(\mathbf{w}) \neq 0$, then $\theta_P(\mathbf{w}) = \infty$. Which means that:

$$\theta_P(\mathbf{w}) = \begin{cases} f(\mathbf{w}) & \text{if primal constraints are satisfied} \\ \infty & \text{otherwise,} \end{cases}$$

Primal and Dual Formulations (II)

Dual Optimization

• Consider θ_D , defined as:

$$\theta_D(\boldsymbol{lpha}, \boldsymbol{eta}) = \underset{\mathbf{w}}{min} L(\mathbf{w}, \boldsymbol{lpha}, \boldsymbol{eta})$$

• The dual optimization problem can be posed as:

$$d^* = \max_{\boldsymbol{\alpha}, \boldsymbol{\beta}: \alpha_i \ge 0} \theta_D(\boldsymbol{\alpha}, \boldsymbol{\beta}) = \max_{\boldsymbol{\alpha}, \boldsymbol{\beta}: \alpha_i \ge 0} \min_{\mathbf{w}} L(\mathbf{w}, \boldsymbol{\alpha}, \boldsymbol{\beta})$$

 $d^* == p^*$?

- Note that $d^* \leq p^*$
- "Max min" of a function is always less than or equal to "Min max"
- When will they be equal?
 - $f(\mathbf{w})$ is convex
 - Constraints are affine

Relation between primal and dual

- In general $d^* \leq p^*$, for SVM optimization the equality holds
- Certain conditions should be true
- Known as the **Kahrun-Kuhn-Tucker** conditions
- For $d^* = p^* = L(\mathbf{w}^*, \boldsymbol{\alpha}^*, \boldsymbol{\beta}^*)$:

$$\frac{\partial}{\partial \mathbf{w}} L(\mathbf{w}^*, \boldsymbol{\alpha}^*, \boldsymbol{\beta}^*) = 0$$

$$\frac{\partial}{\partial \beta_j} L(\mathbf{w}^*, \boldsymbol{\alpha}^*, \boldsymbol{\beta}^*) = 0, \quad j = 1, \dots, l$$

$$\alpha_i^* g_i(\mathbf{w}^*) = 0, \quad i = 1, \dots, k$$

$$g_i(\mathbf{w}^*) \leq 0, \quad i = 1, \dots, k$$

$$\alpha_i^* \geq 0, \quad i = 1, \dots, k$$

Optimization Formulation

minimize
$$\frac{\|\mathbf{w}\|^2}{2}$$

subject to $y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1, \ n = 1, \dots, N.$

A Toy Example

- $\mathbf{x} \in \Re^2$
- Two training points:

$$\mathbf{x}_1, y_1 = (1, 1), -1$$

 $\mathbf{x}_2, y_2 = (2, 2), +1$

• Find the best hyperplane $\mathbf{w} = (w_1, w_2)$

Optimization problem for the toy example

minimize
$$f(\mathbf{w}) = \frac{1}{2} \|\mathbf{w}\|^2$$

subject to $g_1(\mathbf{w}, b) = y_1(\mathbf{w}^{\mathsf{T}} \mathbf{x}_1 + b) - 1 \ge 0$
 $g_2(\mathbf{w}, b) = y_2(\mathbf{w}^{\mathsf{T}} \mathbf{x}_2 + b) - 1 \ge 0.$

• Substituting actual values for \mathbf{x}_1, y_1 and \mathbf{x}_2, y_2 .

minimize
$$f(\mathbf{w}) = \frac{1}{2} ||\mathbf{w}||^2$$

subject to $g_1(\mathbf{w}, b) = -(\mathbf{w}^{\top} \mathbf{x}_1 + b) - 1 \ge 0$
 $g_2(\mathbf{w}, b) = (\mathbf{w}^{\top} \mathbf{x}_2 + b) - 1 \ge 0.$

The above problem can be also written as:

minimize
$$f(w_1, w_2) = \frac{1}{2}(w_1^2 + w_2^2)$$

subject to $g_1(w_1, w_2, b) = -(w_1 + w_2 + b) - 1 \ge 0$
 $g_2(w_1, w_2, b) = (2w_1 + 2w_2 + b) - 1 \ge 0$.

To solve the toy optimization problem, we rewrite it in the Lagrangian form:

$$L(w_1, w_2, b, \alpha) = \frac{1}{2}(w_1^2 + w_2^2) + \alpha_1(w_1 + w_2 + b + 1) - \alpha_2(2w_1 + 2w_2 + b - 1)$$

Setting $\nabla L = 0$, we get:

$$\frac{\partial}{\partial w_1} L(w_1, w_2, b, \alpha) = w_1 + \alpha_1 - 2\alpha_2 = 0$$

$$\frac{\partial}{\partial w_2} L(w_1, w_2, b, \alpha) = w_2 + \alpha_1 - 2\alpha_2 = 0$$

$$\frac{\partial}{\partial b} L(w_1, w_2, b, \alpha) = \alpha_1 - \alpha_2 = 0$$

$$\frac{\partial}{\partial \alpha_1} L(w_1, w_2, b, \alpha) = w_1 + w_2 + b + 1 = 0$$

$$\frac{\partial}{\partial \alpha_2} L(w_1, w_2, b, \alpha) = 2w_1 + 2w_2 + b - 1 = 0$$

Solving the above equations, we get, $w_1 = w_2 = 1$ and b = -3.

Back to SVM Optimization

Optimization Formulation

minimize
$$\frac{\|\mathbf{w}\|^2}{2}$$

subject to $y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1, \ n = 1, \dots, N.$

• Introducing Lagrange Multipliers, α_n , n = 1, ..., N

Rewriting as a (primal) Lagrangian

minimize
$$L_P(\mathbf{w}, b, \alpha) = \frac{\|\mathbf{w}\|^2}{2} + \sum_{n=1}^N \alpha_n \{1 - y_n(\mathbf{w}^\top \mathbf{x}_n + b)\}$$

subject to $\alpha_n \ge 0$ $n = 1, ..., N$.

Solving the Lagrangian

• Set gradient of L_P to 0

$$\frac{\partial L_P}{\partial \mathbf{w}} = 0 \Rightarrow \mathbf{w} = \sum_{n=1}^N \alpha_n y_n \mathbf{x}_n$$

$$\frac{\partial L_P}{\partial b} = 0 \Rightarrow \sum_{n=1}^{N} \alpha_n y_n = 0$$

• Substituting in L_P to get the dual L_D

Dual Lagrangian Formulation

maximize
$$L_D(\mathbf{w}, b, \alpha) = \sum_{n=1}^{N} \alpha_n - \frac{1}{2} \sum_{m,n=1}^{N} \alpha_m \alpha_n y_m y_n (\mathbf{x}_m^{\top} \mathbf{x}_n)$$

subject to $\sum_{n=1}^{N} \alpha_n y_n = 0, \alpha_n \ge 0 \ n = 1, \dots, N.$

- Dual Lagrangian is a quadratic programming problem in α_n 's
 - Use "off-the-shelf" solvers
- Having found α_n 's

$$\mathbf{w} = \sum_{n=1}^{N} \alpha_n y_n \mathbf{x}_n$$

• What will be the bias term b?

Investigating Kahrun Kuhn Tucker Conditions

- For the primal and dual formulations
- We can optimize the dual formulation (as shown earlier)
- Solution should satisfy the **Karush-Kuhn-Tucker** (KKT) Conditions

3.1 Kahrun-Kuhn-Tucker Conditions

$$\frac{\partial}{\partial \mathbf{w}} L_P(\mathbf{w}, b, \alpha) = \mathbf{w} - \sum_{n=1}^{N} \alpha_n y_n \mathbf{x}_n = 0$$
 (3)

$$\frac{\partial}{\partial b} L_P(\mathbf{w}, b, \alpha) = -\sum_{n=1}^{N} \alpha_n y_n = 0$$
 (4)

$$y_n\{\mathbf{w}^{\mathsf{T}}\mathbf{x}_n + b\} - 1 \ge 0 \tag{5}$$

$$\alpha_n \geq 0 \tag{6}$$

$$y_n\{\mathbf{w}^{\top}\mathbf{x}_n + b\} - 1 \geq 0$$

$$\alpha_n \geq 0$$

$$\alpha_n(y_n\{\mathbf{w}^{\top}\mathbf{x}_n + b\} - 1) = 0$$
(5)
$$(6)$$

$$(7)$$

- Use KKT condition #5
- For $\alpha_n > 0$

$$(y_n\{\mathbf{w}^{\top}\mathbf{x}_n + b\} - 1) = 0$$

• Which means that:

$$b = -\frac{\max_{n:y_n = -1} \mathbf{w}^{\mathsf{T}} \mathbf{x}_n + \min_{n:y_n = 1} \mathbf{w}^{\mathsf{T}} \mathbf{x}_n}{2}$$

Support Vectors 3.2

Most α_n 's are 0

• KKT condition #5:

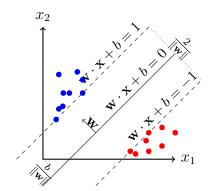

$$\alpha_n(y_n\{\mathbf{w}^\top\mathbf{x}_n + b\} - 1) = 0$$

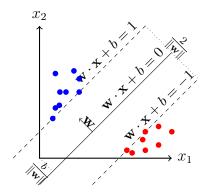

• If \mathbf{x}_n not on margin

$$y_n\{\mathbf{w}^{\top}\mathbf{x}_n + b\} > 1$$

$$\Rightarrow \qquad \alpha_n = 0$$

- $\alpha_n \neq 0$ only for \mathbf{x}_n on margin
- These are the **support vectors**
- Only need these for prediction

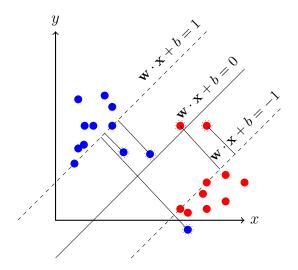

One can see from the prediction equation that:

$$y^* = sign(\sum_{n=1}^{N} \alpha_n y_n \left(\mathbf{x}_n^{\mathsf{T}} \mathbf{x}^* \right) \right)$$

In the summation, the entries for \mathbf{x}_n that do not lie on the margin will have no contribution to the sum because α_n for those \mathbf{x}_n 's will be 0. Hence we only need to the non-zero input examples to get the prediction.

What have we seen so far?

- For linearly separable data, SVM learns a weight vector **w**
- Maximizes the margin
- SVM training is a constrained optimization problem
 - Each training example should lie outside the margin
 - N constraints
- Cannot go for zero training error
- Still learn a maximum margin hyperplane
 - 1. Allow some examples to be misclassified
 - 2. Allow some examples to fall **inside** the margin
- How do you set up the optimization for SVM training

Introducing Slack Variables

• Separable Case: To ensure zero training loss, constraint was

$$y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1 \quad \forall n = 1 \dots N$$

• Non-separable Case: Relax the constraint

$$y_n(\mathbf{w}^{\top}\mathbf{x}_n + b) \ge 1 - \xi_n \quad \forall n = 1 \dots N$$

- ξ_n is called **slack variable** $(\xi_n \ge 0)$
- For misclassification, $\xi_n > 1$

3.3 Optimization Constraints

- It is OK to have some misclassified training examples
 - Some ξ_n 's will be non-zero
- Minimize the number of such examples
 - Minimize $\sum_{n=1}^{N} \xi_n$

• Optimization Problem for Non-Separable Case

minimize
$$f(\mathbf{w}, b) = \|\mathbf{w}\|^2 + C \sum_{n=1}^{N} \xi_n$$

subject to $y_n(\mathbf{w}^{\top} \mathbf{x}_n + b) \ge 1 - \xi_n, \xi_n \ge 0 \ n = 1, \dots, N.$

- ullet C controls the impact of margin and the margin error.
- What is the role of C?
- Similar optimization procedure as for the separable case (QP for the dual)
- Weights have the same expression

$$\mathbf{w} = \sum_{n=1}^{N} \alpha_n y_n \mathbf{x}_n$$

- Support vectors are slightly different
 - 1. Points on the margin $(\xi_n = 0)$
 - 2. Inside the margin but on the correct side $(0 < \xi_n < 1)$
 - 3. On the wrong side of the hyperplane $(\xi_n \ge 1)$

C dictates if we focus more on maximizing the margin or reducing the training error.

- \bullet Training time for SVM training is $O(N^3)$
- Many faster but approximate approaches exist
 - Approximate QP solvers
 - Online training
- SVMs can be extended in different ways
 - 1. Non-linear boundaries (kernel trick)
 - 2. Multi-class classification
 - 3. Probabilistic output
 - 4. Regression (Support Vector Regression)
